

# Alpha Forge Bitcoin Alpha Report

On-chain and macro ML modelling

## What I did

I cleaned the daily Bitcoin dataset, built the Rhode feature set, created a next-day log return target, trained several simple machine learning models, turned the best validation model into a daily long/short signal, and tested it against Bitcoin buy-and-hold. The split is chronological, so later rows never leak into earlier training.

| Item              | Value                    |
|-------------------|--------------------------|
| Raw rows          | 4,292                    |
| Usable model rows | 4,261                    |
| Model date range  | 2014-10-17 to 2026-06-16 |
| Train             | 2014-10-17 to 2022-12-15 |
| Validation        | 2022-12-16 to 2024-09-14 |
| Test              | 2024-09-15 to 2026-06-16 |

## Main result

The selected model was **Ridge alpha 80**, chosen on the validation set by the best strategy Sharpe ratio. On the untouched test period, it reached directional accuracy of 50.16%, an annualized Sharpe ratio of 0.60, and cumulative strategy return of 34.54%. Bitcoin buy-and-hold over the same test rows returned 8.81%.

## Test metrics

| Model              | MAE     | RMSE    | Dir.  | R2     | Sharpe | Max DD | Strategy | BTC  |
|--------------------|---------|---------|-------|--------|--------|--------|----------|------|
| Mean baseline      | 0.01679 | 0.02378 | 49.8% | -0.002 | 0.33   | -51.2% | 8.8%     | 8.8% |
| Boosted stumps 40  | 0.01699 | 0.02396 | 50.2% | -0.017 | 0.33   | -51.2% | 8.8%     | 8.8% |
| Boosted stumps 80  | 0.01733 | 0.02424 | 50.2% | -0.042 | 0.33   | -51.2% | 8.8%     | 8.8% |
| Boosted stumps 120 | 0.01739 | 0.02429 | 50.2% | -0.046 | 0.33   | -51.2% | 8.8%     | 8.8% |
| Ridge alpha 80     | 0.01969 | 0.02620 | 50.2% | -0.216 | 0.60   | -43.1% | 34.5%    | 8.8% |
| Ridge alpha 20     | 0.02027 | 0.02673 | 50.2% | -0.266 | 0.33   | -51.2% | 8.8%     | 8.8% |
| Ridge alpha 5      | 0.02046 | 0.02690 | 50.2% | -0.283 | 0.33   | -51.2% | 8.8%     | 8.8% |
| Ridge alpha 1      | 0.02052 | 0.02695 | 50.2% | -0.288 | 0.33   | -51.2% | 8.8%     | 8.8% |

## Feature checks

| Feature            | Correlation with next-day return |
|--------------------|----------------------------------|
| 10Y Treasury yield | -0.0227                          |
| Active addresses   | 0.0227                           |
| Fee to market cap  | 0.0216                           |
| True Market Cap    | -0.0203                          |
| Rolling volatility | 0.0147                           |
| Hash rate          | -0.0134                          |
| Fees in USD        | 0.0076                           |
| US Dollar Index    | -0.0040                          |

The raw correlations are weak, which is normal for daily Bitcoin returns. This means the model should be judged more by out-of-sample performance than by any single correlation value.

## Market regimes

| Regime        | Days  | Avg next return | Vol.  | DXY    | TNX  | Active addr. |
|---------------|-------|-----------------|-------|--------|------|--------------|
| Bear          | 757   | 0.022%          | 3.82% | 97.51  | 2.64 | 697,625      |
| Bull          | 1,331 | 0.293%          | 4.06% | 97.64  | 2.50 | 820,171      |
| Consolidation | 1,881 | 0.109%          | 2.90% | 98.73  | 2.86 | 704,132      |
| Macro shock   | 202   | -0.194%         | 2.63% | 102.76 | 2.95 | 754,903      |

## Feature importance

| Feature            | Model weight | RMSE increase when shuffled |
|--------------------|--------------|-----------------------------|
| Active addresses   | 0.373        | 0.000112                    |
| True Market Cap    | 0.337        | 0.000044                    |
| Rolling volatility | 0.065        | 0.000006                    |
| Fee to market cap  | 0.016        | -0.000000                   |
| Hash rate          | 0.022        | -0.000002                   |
| 10Y Treasury yield | 0.070        | -0.000002                   |
| US Dollar Index    | 0.039        | -0.000007                   |
| Fees in USD        | 0.078        | -0.000018                   |

The strongest feature by permutation testing was **Active addresses**. This does not mean it predicts every day by itself. It means the trained model lost the most accuracy when that input was disturbed.

## Data preparation notes

I used the eight input Rhode features and built 30-day rolling volatility from past log returns. Large on-chain values were log-transformed, then all model inputs were standardized using only the training period. The target was next-day log return. This lets the signal be used after today's close without seeing tomorrow's price. The long/short cutoff was calibrated on the validation period, then held fixed for the test period.

## Conclusion

The signal is useful as a research alpha, not as a finished trading system. It shows that on-chain activity, network valuation, macro conditions, and volatility contain some information about the next day's return direction. The main weakness is that daily Bitcoin returns are noisy, so small statistical gains can disappear after trading costs, slippage, or regime changes. A production version should add transaction costs, position sizing, walk-forward retraining, and stricter risk limits.
